Direct detection of Dark Matter particles in the galactic halo

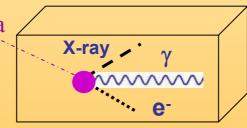

- Various approaches and techniques (many still at R&D stage)
- ➤ Various different target nuclei
- Various different experimental site depths

scatterings on nuclei

- → detection of nuclear recoil energy
- conversion of particle into electromagnetic radiation
 - \rightarrow detection of γ , X-rays, e⁻¹

- excitation of bound electrons in scatterings on nuclei
 - → detection of recoil nuclei + e.m. radiation

NOTE: signals from these candidates are lost in experiments based on rejection procedures of the electromagnetic events

A model independent signature is needed

Directionality Correlation of nuclear recoil track with Earth's galactic motion due to the distribution of Dark Matter particles velocities very hard to realize

Nuclear-inelastic scattering
Detection of γ 's emitted by
excited nucleus after a nuclearinelastic scattering.
very large exposure and very low
counting rates hard to realize

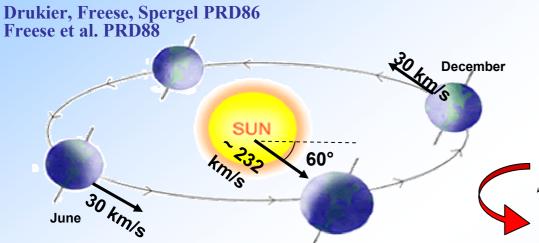

Diurnal modulation Daily variation of the interaction rate due to different Earth depth crossed by the Dark Matter particles only for high o

Annual modulation Annual variation of the interaction rate due to Earth motion around the Sun.

at present the only feasible one

The annual modulation: a model independent signature for the investigation of Dark Matter particles component in the galactic halo

With the present technology, the annual modulation is the main model independent signature for the DM signal. Although the modulation effect is expected to be relatively small a suitable large-mass, low-radioactive set-up with an efficient control of the running conditions would point out its presence.

Requirements of the annual modulation

- 1) Modulated rate according cosine
- 2) In a definite low energy range
- 3) With a proper period (1 year)
- 4) With proper phase (about 2 June)
- 5) For single hit events in a multi-detector set-up
- 6) With modulation amplitude in the region of maximal sensitivity must be <7% for usually adopted halo distributions, but it can be larger in case of some possible scenarios

- · v_{sun} ~ 232 km/s (Sun velocity in the halo)
- · v_{orb} = 30 km/s (Earth velocity around the Sun)
- $\gamma = \pi/3$
- $\cdot \omega = 2\pi/T$ T = 1 year
- t_0 = 2^{nd} June (when v_{\oplus} is maximum)

$$v_{\oplus}(t) = v_{\text{sun}} + v_{\text{orb}} \cos \gamma \cos[\omega(t-t_0)]$$

$$S_k[\eta(t)] = \int_{\Delta E_k} \frac{dR}{dE_R} dE_R \cong S_{0,k} + S_{m,k} \cos[\omega(t - t_0)]$$

Expected rate in given energy bin changes because the annual motion of the Earth around the Sun moving in the Galaxy

To mimic this signature, spurious effects and side reactions must not only - obviously - be able to account for the whole observed modulation amplitude, but also to satisfy contemporaneously all the requirements

Competitiveness of NaI(TI) set-up

- High duty cycle
- Well known technology
- Large mass possible
- "Ecological clean" set-up; no safety problems
- Cheaper than every other considered technique
- Small underground space needed
- High radiopurity by selections, chem./phys. purifications, protocols reachable
- Well controlled operational condition feasible
- Routine calibrations feasible down to keV range in the same conditions as the production runs
- Neither re-purification procedures nor cooling down/warming up (reproducibility, stability, ...)
- Absence of microphonic noise + effective noise rejection at threshold (τ of NaI(Tl) pulses hundreds ns, while τ of noise pulses tens ns)
- High light response (5.5 -7.5 ph.e./keV)
- Sensitive to SI, SD, SI&SD couplings and to other existing scenarios, on the contrary of many other proposed target-nuclei
- Sensitive to both high (by Iodine target) and low mass (by Na target) candidates
- Effective investigation of the annual modulation signature feasible in all the needed aspects
- PSD feasible at reasonable level
- etc.

<u>A low background NaI(Tl) also allows</u> the study of several other rare processes such as: possible processes violating the Pauli exclusion principle, CNC processes in ²³Na and ¹²⁷I, electron stability, nucleon and dinucleon decay into invisible channels, neutral SIMP and nuclearites search, solar axion search, ...

- Reduced standard contaminants (e.g. U/Th of order of ppt) by material selection and growth/handling protocols.
- PMTs: Each crystal coupled through 10cm long tetrasil-B light guides acting as optical windows to 2 low background EMI9265B53/FL (special development) 3" diameter PMTs working in coincidence.
- Detectors inside a sealed Cu box maintained in HP Nitrogen atmosphere in slight overpressure
- Very low radioactive shields: 10 cm of Cu, 15 cm of Pb + shield from neutrons: Cd foils + polyethylene/paraffin+ ~ 1 m concrete moderator largely surrounding the set-up
- Installation sealed: A plexiglas box encloses the whole shield and is also maintained in HP Nitrogen atmosphere in slight overpressure. Walls, floor, etc. of inner installation sealed by Supronyl (2×10^{-11} cm²/s permeability). Three levels of sealing.
- Installation in air conditioning + huge heat capacity of shield
- Calibration using the upper glove-box (equipped with compensation chamber) in HP Nitrogen atmosphere in slight overpressure calibration \rightarrow in the same running conditions as the production runs.
- Energy and threshold: Each PMT works at single photoelectron level. Energy threshold: 2 keV (from X-ray and Compton electron calibrations in the keV range and from the features of the noise rejection and efficiencies). Data collected from low energy up to MeV region, despite the hardware optimization was done for the low energy
- Pulse shape recorded over 3250 ns by Transient Digitizers.
- Monitoring and alarm system continuously operating by self-controlled computer processes.

+ electronics and DAQ fully renewed in summer 2000

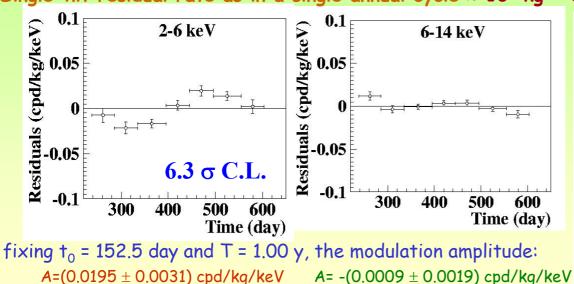

Main procedures of the DAMA data taking for the DMp annual modulation signature

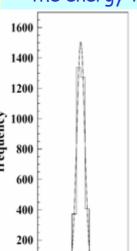

- data taking of each annual cycle starts from autumn/winter (when $\cos\omega(t-t_0)\approx 0$) toward summer (maximum expected).
- routine calibrations for energy scale determination, for acceptance windows efficiencies by means of radioactive sources each ~ 10 days collecting typically $\sim 10^5$ evts/keV/detector + intrinsic calibration from 210 Pb (~ 7 days periods) + periodical Compton calibrations, etc.
- continuous on-line monitoring of all the running parameters with automatic alarm to operator if any out of allowed range.

Low energy vs higher energy

Single-hit residual rate as in a single annual cycle $\approx 10^5$ kg × day Power spectrum of single-hit

• Clear modulation present in the lowest energy region: from the energy threshold, 2 keV, to 6 keV.

 $(R_{00} - \langle R_{00} \rangle)/\langle R_{00} \rangle$

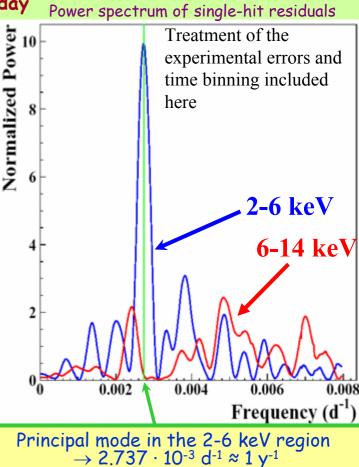

- No modulation found:
 - ·in the 6-14 keV energy regions
 - · in other energy regions closer to that where the effect is observed e.g.: mod.

where the effect is observed e.g.: mode ampl. (6-10 keV): $-(0.0076 \pm 0.0065)$, (0.0012 ± 0.0059) and (0.0035 ± 0.0058)

cpd/kg/keV for DAMA/NaI-5, DAMA/NaI-6 and DAMA/NaI-7; statistically consistent

6 and DAMA/NaI-7; statistically consistent with zero

•in the integral rate above 90 keV, e.g.: mod. ampl.: (0.09±0.32), (0.06±0.33) and - (0.03±0.32) cpd/kg for DAMA/NaI-5, DAMA/NaI-6 and DAMA/NaI-7; statistically consistent with zero + if a modulation present in the whole energy spectrum at the level found in the lowest energy region $\rightarrow R_{90} \sim \text{tens cpd/kg} \rightarrow \sim 100 \text{ }\sigma$ far away

Not present in the 6-14 keV region (only aliasing peaks)

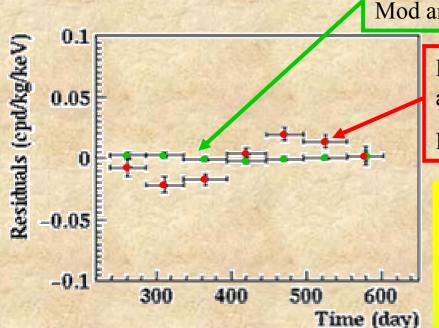

Multiple-hits events in the region of the signal

- In DAMA/NaI-6 and 7 each detector has its own TD (multiplexer system removed) → pulse profiles of multiple-hits events (multiplicity > 1) also acquired (total exposure: 33834 kg d).
- The same hardware and software procedures as the ones followed for single-hit events
 - → just one difference: events induced by Dark Matter particles do not belong to this class of events, that is: multiple-hits events = Dark Matter particles events "switched off"

Residuals for multiple-hits events (DAMA/NaI-6 and 7)

Mod ampl. = $-(3.9\pm7.9) \cdot 10^{-4} \text{ cpd/kg/keV}$

Residuals for single-hit events (DAMA/NaI 7 annual cycles)

Mod ampl. = (0.0195 ± 0.0031) cpd/kg/keV

This result offers an additional strong support for the presence of Dark Matter particles in the galactic halo further excluding any side effect either from hardware or from software procedures or from background

Summary of the results obtained in the investigations of possible systematics or side reactions

modulation effect

annual modulation signature

Summary of the DAMA/NaI Model Independent result

Presence of modulation for 7 annual cycles at ~6.3σ C.L. with the proper distinctive features of the signature; all the features satisfied by the data over 7 independent experiments of 1 year each one

Absence of known sources of possible systematics and side processes able to quantitatively account for the observed effect and to contemporaneously satisfy the many peculiarities of the signature

No other experiment whose result can be directly compared in model independent way is available so far

To investigate the nature and coupling with ordinary matter of the possible DM candidate(s), effective energy and time correlation analysis of the events has to be performed within given model frameworks

Corollary quests for candidate(s)

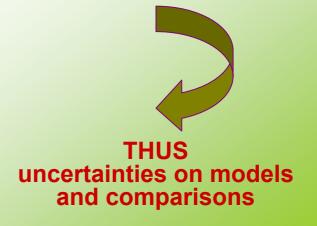

astrophysical models: ρ_{DM} , velocity distribution and its parameters

nuclear and particle Physics models

experimental parameters

e.g. for WIMP class particles: SI, SD, mixed SI&SD, preferred inelastic, scaling laws on cross sections, form factors and related parameters, spin factors, halo models, etc.

- + different scenarios
- + multicomponent?

First case: the case of DM particle scatterings on target-nuclei. The recoil energy is the detected quantity

DM particle-nucleus elastic scattering

$$\frac{d\sigma}{dE_R}(v, E_R) = \left(\frac{d\sigma}{dE_R}\right) + \left(\frac{d\sigma}{dE_R}\right) =$$

$$\frac{2G_F^2 m_N}{\pi v^2} \left\{ \left[Zg_p + (A - Z)g_n \right]^2 F_{SI}^2(E_R) + 8 \frac{J+1}{I} \left[a_p \langle S_p \rangle + a_n \langle S_n \rangle \right]^2 F_{SD}^2(E_R) \right\}$$

SI+SD differential cross sections:

 $g_{p,n}(a_{p,n})$ effective DM particle-nucleon couplings

 $\langle S_{p,n} \rangle$ nucleon spin in the nucleus

 $F^2(E_D)$ nuclear form factors

 m_{Wp} reduced DM particle-nucleon mass

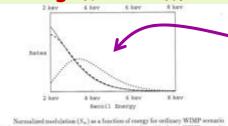

Note: not universal description. Scaling laws assumed to define point-like cross sections from nuclear ones. Four free parameters: $m_{W'}$, σ_{SI} , σ_{SD} , $tg\theta = \frac{a_n}{a_n}$

Preferred inelastic DM particle-nucleus scattering: $\chi_+ + N \rightarrow \chi_+ + N$

- DM particle candidate suggested by D. Smith and N. Weiner (PRD64(2001)043502)
- Two mass states χ_{\perp} , χ_{\perp} with δ mass splitting
- Kinematical constraint for the inelastic scattering of $\chi_{\scriptscriptstyle -}$ on a nucleus with mass m_N becomes increasingly severe for low mn

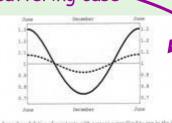

$$\frac{1}{2}\mu v^2 \ge \delta \Leftrightarrow v \ge v_{thr} = \sqrt{\frac{2\delta}{\mu}}$$

Three free parameters: $m_{W'}$, $\sigma_{n'}$, δ

	Ex.	m _W	=100 G	eV
1	m	N	μ	
١	7	0	41	
ı	13	0	57	

 S_m/S_0 enhanced with respect to the elastic scattering case -

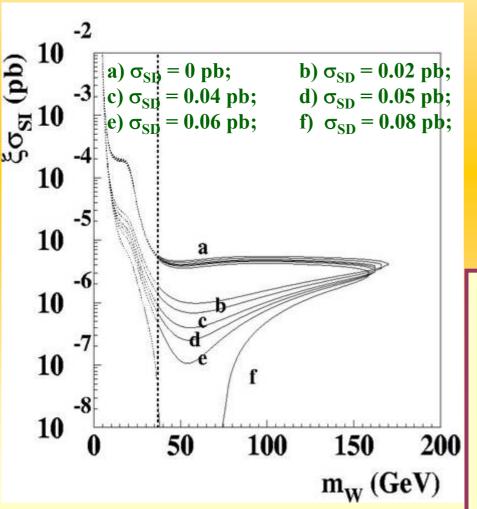

Differential energy distribution depends on the assumed scaling laws, nuclear form factors, spin factors, free parameters (\rightarrow kind of coupling, mixed SI&SD, pure SI, pure SD, pure SD through Z_0 exchange, pure SD with dominant coupling on proton, pure SD with dominant coupling on neutron, preferred

inelastic, ...), on the assumed astrophysical model (halo model, presence of non-thermalized components, particle velocity distribution, particle density in the halo, ...) and on instrumental quantities (quenching factors, energy resolution, efficiency, ...)

An example of the effect induced by a non-zero SD component on the allowed SI regions

- Example obtained considering Evans' logarithmic axisymmetric C2 halo model with v_0 = 170 km/s, ρ_0 max at a given set of parameters
- The different regions refer to different SD contributions with θ =0

A small SD contribution \Rightarrow drastically moves the allowed region in the plane (m_W, $\xi \sigma_{SI}$) towards lower SI cross sections ($\xi \sigma_{SI} < 10^{-6}$ pb)

Similar effect for whatever considered model framework

- There is no meaning in bare comparison between regions allowed in experiments sensitive to SD coupling and exclusion plots achieved by experiments that are not.
- The same is when comparing regions allowed by experiments whose target-nuclei have unpaired proton with exclusion plots quoted by experiments using target-nuclei with unpaired neutron where $\theta \approx 0$ or $\theta \approx \pi$.

Supersymmetric expectations in MSSM

- Assuming for the neutralino a dominant purely SI coupling
- •when releasing the gaugino mass unification at GUT scale: $M_1/M_2 \neq 0.5$ (<);

(where M_1 and M_2 U(1) and SU(2) gaugino masses)

Example of joint analysis of DAMA/NaI and positron/gamma's excess in the space in the light of two DM particle components in the halo

Another class of DM candidates: light bosonic particle IJMPA21(2006)1445

Axion-like particles: similar phenomenology with ordinary matter as the axion, but significantly different values for mass and coupling constants are allowed.

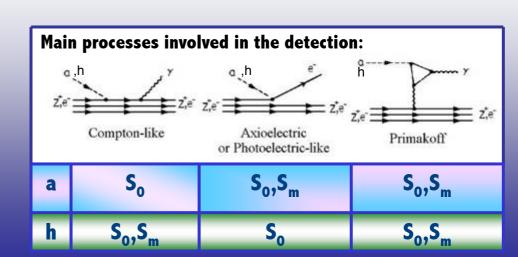

A wide literature is available and various candidate particles have been and can be considered.

The detection is based on the total conversion of the absorbed bosonic mass into electromagnetic radiation.

In these processes the target nuclear recoil is negligible and not involved in the detection process (i.e. signals from these candidates are lost in experiments applying rejection procedures of the electromagnetic contribution)

A complete data analysis of the total 107731 kgxday exposure from DAMA/Nal has been performed for pseudoscalar (a) and scalar (h) candidates in some of the possible scenarios.

They can account for the DAMA/Nal observed effect as well as candidates belonging to the WIMPs class

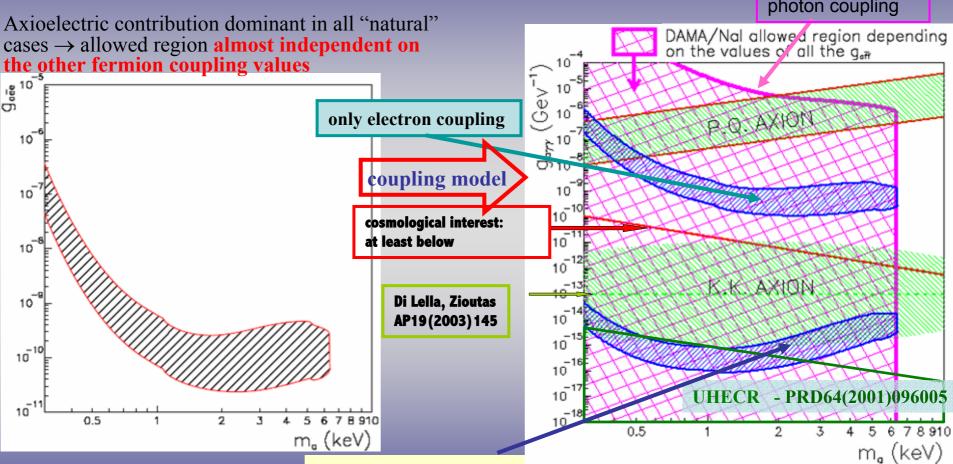

The pseudoscalar case

Analysis of 107731 kg day exposure from DAMA/Nal.

IJMPA21(2006)1445

Allowed multi-dimensional volume in the space defined by m_a and all coupling constants to charged fermions (3 σ C.L.) in the given frameworks

Maximum allowed photon coupling

Majoron as in PLB99(1981)411; coupling to photons vanish at first order:

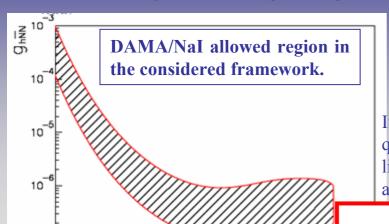

$$g_{a\gamma\gamma} \approx \frac{\alpha}{\pi} \left[\frac{g_{a\bar{e}e}}{m_e} + 3 \frac{\frac{1}{9} g_{a\bar{d}d}}{m_d} + 3 \frac{\frac{4}{9} g_{a\bar{u}u}}{m_u} \right] \approx 0 \left(\frac{g_{a\bar{e}e}}{m_e} = \frac{g_{a\bar{d}d}}{m_d} = -\frac{g_{a\bar{u}u}}{m_u} \right)$$

Also this can account for the DAMA/Nal observed effect

The scalar case

Allowed multi-dimensional volume in the space defined by m_h and all the coupling

- 1) electron coupling does not provide modulation
- 2) from measured rate: g_{hee} < 3 10^{-16} to 10^{-14} for $m_h \approx 0.5$ to 10 keV
- 3) coupling only to hadronic matter: allowed region in $g_{h\overline{N}N}$ vs. m_h $(3\sigma C.L.)$

If all the couplings to quarks of the same order: 20.2 lifetime dominated by u 0.15 and d loops:

$$g_{h\bar{N}N} = (g_{h\bar{u}u} + 2g_{h\bar{d}d}) + \frac{Z}{A}(g_{h\bar{u}u} - g_{h\bar{d}d})$$

 $g_{h\gamma\gamma} pprox \sum_{\alpha} -\frac{2}{3} \frac{\alpha}{\pi} \frac{Q_q^2 g_{h\overline{q}q}}{\pi m_{\alpha}} pprox -2 \frac{\alpha}{\pi} \left| \frac{\frac{4}{9} g_{h\overline{u}u}}{m_u} + \frac{\frac{1}{9} g_{h\overline{d}d}}{m_d} \right|$

h configurations of cosmological interest in $g_{h\overline{u}u}$ vs $g_{h\overline{d}d}$ plane

-0.15

Many other configurations of cosmological interest are possible depending on the values of the couplings to other quarks and to gluons....

- Annual modulation signature present for a scalar particle with pure coupling to hadronic matter (possible gluon coupling at tree level?).
- process for particle with cosmological lifetime.

0.05

• $m_n = 3.0 \pm 1.5 \text{ MeV}$ $m_d = 6.0 \pm 2.0 \text{ MeV}$

Also this can account for the DAMA/Nal observed effect

The new DAMA/LIBRA set-up ~250 kg NaI(Tl) (Large sodium Iodide Bulk for RAre processes)

Stability of the high energy calibration factors

March 2003 – April 2005

Summary

DAMA/NaI data show a 6.30 C.L. model independent evidence for the presence of a Dark Matter particle component in the galactic halo

- Corollary model dependent quest for the candidate particle:
- WIMP particles with m_w^{\sim} (few GeV to TeV) with coupling pure SI or pure SD or mixed SI/SD as well as particles with preferred inelastic scattering
- (Riv.N.Cim. 26 n.1. (2003) 1-73, ITMPD 13 (2004) 2127)

 several other particles suggested in literature by various authors
- bosonic particles with m_a~ keV having pseudoscalar, scalar coupling (IJMPA21(2006)1445)
- halo substructures (SagDEG) effects (astro-ph/p604303, EPJC in press)
- · and more in progress...

The presently running DAMA/LIBRA will allow to further increase the C.L. of the model independent result, to restrict the nature of the candidate and to investigate the phase space structure of the dark halo

+ a new R&D towards a possible ton set-up we proposed in 1996 in progress ... wait for more in the near future
